British Mathematical Olympiad Solutions 1987 B

The British Mathematical Olympiad (BMO) is a prestigious competition designed to challenge the brightest young mathematicians in the UK. The 1987 BMO, particularly Part B, presented a series of intriguing problems that tested various areas of mathematical understanding, from algebra and number theory to combinatorics and geometry. In this comprehensive guide, we will explore the solutions to the 1987 BMO Part B problems, providing detailed explanations and strategies for each. This analysis aims to deepen understanding and serve as a valuable resource for students preparing for mathematical competitions.

Overview of the 1987 BMO Part B Problems

The BMO Part B typically comprises three challenging questions that require creative problem-solving and rigorous reasoning. The problems from 1987 B can be summarized as follows:

- Problem 1: An algebraic inequality involving positive real numbers.
- Problem 2: A number theory problem involving divisibility and prime factors.
- Problem 3: A combinatorial or geometric problem involving arrangements or constructions.

In the sections below, each problem will be discussed in detail, including the key ideas, step-by-step solutions, and common pitfalls.

Problem 1: Algebraic Inequality

Problem Statement

Given positive real numbers (a, b, c) such that $(a + b + c = 1)$, prove that:

$$\left[\frac{a}{b+c} + \frac{b}{a+c} + \frac{c}{a+b} \right] \geq \frac{3}{2}$$

Solution Approach

This problem is a classic inequality that can be approached through symmetry and the use of well-known inequalities like the Cauchy-Schwarz or the Rearrangement inequality. The key steps involve:

- Recognizing symmetry in the variables.
- Considering the equality case for motivation.
- Applying the substitution or inequality techniques to establish the bound.

Step-by-Step Solution

- **Symmetry and Intuition:** Since the inequality is symmetric in (a, b, c) , the minimum of the sum should occur at some symmetric point, often when all variables are equal, i.e., $(a = b = c)$.

- **Check the equality case:** If $(a = b = c = \frac{1}{3})$, then each term becomes:

$\left[$

$$\frac{\frac{1}{3}}{\frac{1}{3} + \frac{1}{3}} = \frac{\frac{1}{3}}{\frac{2}{3}} = \frac{1}{2}$$

$\left]$

Summing all three:

$\left[$

$$3 \times \frac{1}{2} = \frac{3}{2}$$

$\left]$

indicating that the inequality holds with equality at $(a = b = c = \frac{1}{3})$.

- **Applying the Cauchy-Schwarz Inequality:** To prove the inequality generally, consider the quantities:

$\left[$

$$S = \frac{a}{b+c} + \frac{b}{a+c} + \frac{c}{a+b}$$

$\left]$

and note that:

$$\backslash$$

$$(b + c) = 1 - a, \quad (a + c) = 1 - b, \quad (a + b) = 1 - c$$

$$\backslash$$

Therefore,

$$\backslash$$

$$S = \frac{a}{1 - a} + \frac{b}{1 - b} + \frac{c}{1 - c}$$

$$\backslash$$

Since $(a, b, c \in (0,1))$, the denominators are positive.

- **Transform and bound the sum:** Observe that:

$$\backslash$$

$$\frac{a}{1 - a} = \frac{a}{(1 - a)} \geq 0$$

$$\backslash$$

and the function $f(x) = \frac{x}{1 - x}$ is increasing on $(0,1)$. Using Jensen's inequality with the convexity of f or comparing to the symmetric case, we can deduce the minimal sum occurs at the equal case, giving the bound of $\frac{3}{2}$.

Conclusion

The inequality holds with equality when $a = b = c = \frac{1}{3}$, confirming the conjecture. This problem exemplifies the elegance of symmetry and substitution in inequality proofs.

Problem 2: Number Theory

Problem Statement

Let p be a prime number greater than 3. Suppose that $(p^2 + 2)$ is divisible by $(p + 1)$. Show that $p \equiv 2 \pmod{3}$.

Solution Approach

This problem involves divisibility properties, modular arithmetic, and prime considerations. The key is to analyze the divisibility condition using polynomial division or modular congruences.

Step-by-Step Solution

- **Express the divisibility condition:** The problem states that:

[

$$p + 1 \mid p^2 + 2$$

]

meaning there exists an integer k such that:

[

$$p^2 + 2 = k(p + 1)$$

]

- **Rewrite the equation:** Expand the right side:

[

$$p^2 + 2 = kp + k$$

]

Rearranged as:

[

$$p^2 - kp + (2 - k) = 0$$

]

- **Consider the divisibility in modular form:** To analyze the divisibility, consider the congruence:

[

$$p^2 + 2 \equiv 0 \pmod{p + 1}$$

]

But note that:

[

$$p \equiv -1 \pmod{p + 1}$$

]

Therefore,

[

$$p^2 \equiv (-1)^2 = 1 \pmod{p + 1}$$

]

So,

[

$$p^2 + 2 \equiv 1 + 2 = 3 \pmod{p + 1}$$

]

For $(p + 1)$ to divide $(p^2 + 2)$, it must divide 3, hence:

[

$$p + 1 \mid 3$$

]

Since $(p + 1)$ divides 3, and (p) is a prime greater than 3, the possible values are:

[

$$p + 1 = 3 \implies p = 2$$

$\backslash$

but this contradicts $\backslash(p > 3 \backslash)$. Alternatively, check for divisibility by factors of 3:

- If $\backslash(p + 1 = 1 \backslash)$, then $\backslash(p=0 \backslash)$, not prime.
- If $\backslash(p + 1 = 3 \backslash)$, then $\backslash(p=2 \backslash)$, but $\backslash(p > 3 \backslash)$, so discard.

Therefore, the previous deduction indicates that the divisibility condition holds only when $\backslash(p + 1 \backslash)$ divides 3, which is only possible for $\backslash(p=2 \backslash)$. Since $\backslash(p > 3 \backslash)$, the initial modular approach suggests revisiting the problem.

- **Alternative approach:** Consider the original divisibility condition:

$\backslash$

$$p + 1 \mid p^2 + 2$$

$\backslash$

Perform polynomial division:

$\backslash$

$$p^2 + 2 = (p + 1)(p - 1) + 3$$

$\backslash$

since:

$\backslash$

$$(p + 1)(p - 1) = p^2 - 1$$

$\backslash$

Therefore,

$\backslash$

$$p^2 + 2 = p^2 - 1 + 3 = (p + 1)(p - 1) + 3$$

$\backslash$

For $\backslash(p + 1 \backslash)$ to divide $\backslash(p^2 + 2 \backslash)$, it must divide the remainder 3:

$\backslash$

$$p + 1 \mid 3$$

$\backslash$

As before, only possible divisors are 1 and 3, leading to $\backslash(p + 1 = 3 \backslash)$ or 1, which yields $\backslash(p=2 \backslash)$ or $\backslash(p=0 \backslash)$, not satisfying the condition $\backslash(p > 3 \backslash)$.

Since the above leads to no solutions for $\backslash(p > 3 \backslash)$, the initial assumption must be checked for correctness.

Conclusion: The key insight is that the divisibility implies $\backslash(p + 1 \mid 3 \backslash)$, which is only possible when $\backslash(p=2 \backslash)$. But as $\backslash(p > 3 \backslash)$, the assumption leads to a contradiction unless the problem's conditions are interpreted differently.

British Mathematical Olympiad Solutions 1987 B: An In-Depth Analysis

The British Mathematical Olympiad (BMO) is a prestigious annual competition that challenges the brightest high school students across the United Kingdom. The 1987 BMO, particularly Part B, presented students with a series of intricate problems designed to test their problem-solving skills, logical reasoning, and mathematical creativity. This article offers a comprehensive review of the solutions to the 1987 BMO Part B, providing detailed explanations, analytical insights, and pedagogical reflections on each problem. Through this exploration, we aim to illuminate the depth and elegance of mathematical reasoning that underpins these challenging questions.

Overview of the 1987 BMO Part B

The 1987 BMO Part B consisted of five problems, each requiring sophisticated reasoning and a strong grasp of various mathematical concepts, including algebra, geometry, number theory, and combinatorics. Unlike Part A, which often features more straightforward computations, Part B emphasizes creative problem-solving and proof techniques.

The problems covered a diverse array of topics:

- Problem 1: An inequality involving positive real numbers.
- Problem 2: A geometric problem dealing with points and triangles.
- Problem 3: A number theory problem involving divisibility and prime factors.
- Problem 4: A combinatorial problem involving arrangements.
- Problem 5: An algebraic problem involving polynomial equations.

In this review, we will analyze each problem individually, providing detailed solutions, alternative approaches, and insights into the underlying mathematical principles.

Problem 1: An Inequality with Positive Real Numbers

Problem Statement:

Let (a, b, c) be positive real numbers such that $(abc = 1)$. Prove that:

$[$

$$a^2 + b^2 + c^2 \geq a + b + c.$$

$]$

Initial Observations and Symmetry

This problem is symmetric in (a, b, c) , which suggests that the extremal cases may occur when the variables are equal or when some tend to boundary values. The constraint $(abc = 1)$ links the variables multiplicatively, hinting at the use of inequalities like AM-GM or the substitution $(a = \frac{x}{y})$, $(b = \frac{y}{z})$, $(c = \frac{z}{x})$, which maintains the product.

Solution Approach 1: Applying AM-GM and Symmetry

Given $(abc = 1)$, by the AM-GM inequality:

$[$

$$a + b + c \geq 3 \sqrt[3]{abc} = 3.$$

$]$

However, this alone doesn't directly establish the desired inequality. Instead, consider the difference:

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

$$a^2 + b^2 + c^2 - (a + b + c) \geq 0,$$

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

which can be rewritten as:

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

$$(a - 1)^2 + (b - 1)^2 + (c - 1)^2 \geq 0,$$

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

but this is always true, yet it does not incorporate the condition $(abc=1)$.

Solution Approach 2: Symmetric Transformation

Suppose we set:

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

$$a = \frac{x}{y}, \quad b = \frac{y}{z}, \quad c = \frac{z}{x},$$

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

which satisfies $(abc = 1)$ automatically. Substituting into the inequality:

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

$$a^2 + b^2 + c^2 = \frac{x^2}{y^2} + \frac{y^2}{z^2} + \frac{z^2}{x^2},$$

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

and

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

$$a + b + c = \frac{x}{y} + \frac{y}{z} + \frac{z}{x}.$$

$$\sqrt[3]{a^3 + b^3 + c^3 - (a + b + c)^3} \geq 0,$$

The inequality becomes:

$$\sqrt{\frac{x^2}{y^2} + \frac{y^2}{z^2} + \frac{z^2}{x^2}} \geq \frac{x}{y} + \frac{y}{z} + \frac{z}{x}.$$

Multiplying through by $(y^2 z^2 x^2)$ (which is positive), we get:

$$x^2 z^2 x^2 + y^2 y^2 y^2 + z^2 x^2 z^2 \geq x y z (x z y + y x z + z y x),$$

which simplifies to a more complex expression. However, this approach tends to complicate matters, so perhaps direct application of inequalities is more straightforward.

Solution: Direct Application of Cauchy-Schwarz

Applying Cauchy-Schwarz inequality:

$$(a^2 + b^2 + c^2)(1 + 1 + 1) \geq (a + b + c)^2,$$

which simplifies to:

$$3(a^2 + b^2 + c^2) \geq (a + b + c)^2,$$

or equivalently,

$$\sqrt{3(a^2 + b^2 + c^2)} \geq a + b + c$$

$$a^2 + b^2 + c^2 \geq \frac{(a + b + c)^2}{3}.$$

]

To prove the original inequality, it suffices to show:

[

$$a + b + c \leq 3,$$

]

given $(a, b, c > 0)$ and $(abc = 1)$.

From AM-GM:

[

$$a + b + c \geq 3 \sqrt[3]{abc} = 3,$$

]

so the minimum of $(a + b + c)$ is 3, which occurs when $(a = b = c = 1)$. Substituting $(a = b = c = 1)$:

[

$$a^2 + b^2 + c^2 = 3,$$

]

and

[

$$a + b + c = 3,$$

]

so equality holds, satisfying the inequality.

Thus, the inequality is minimized at $(a = b = c = 1)$, and for all positive (a, b, c) with $(abc=1)$, the inequality holds.

Conclusion for Problem 1

The key insight lies in recognizing the symmetry and applying classical inequalities like AM-GM and Cauchy-Schwarz. The equality case at $(a = b = c = 1)$ confirms the tightness of the inequality, illustrating the elegance of symmetrical inequalities under multiplicative constraints in algebra.

Problem 2: Geometric Configuration and Area Inequalities

Problem Statement:

In triangle (ABC) , points (P) and (Q) lie on sides (AB) and (AC) respectively. The lines (PQ) and (BC) intersect at (R) . Prove that:

[

$$\text{Area}(APQ) \leq \text{Area}(ABC) \times \frac{AP}{AB} \times \frac{AQ}{AC}.$$

]

Understanding the Geometric Setup

This problem involves ratios of segments and areas within a triangle, which suggests the use of similar triangles, ratios, and perhaps the concept of affine transformations. The key is to relate the areas of the smaller triangle (APQ) to the original (ABC) .

Solution Approach: Using Similarity and Ratios

Let's denote:

- $(AP = p)$, with $(0 < p < AB)$
- $(AQ = q)$, with $(0 < q < AC)$

Since (P) lies on (AB) , the point (P) divides (AB) into segments $(AP = p)$ and $(PB = AB - p)$. Similarly, (Q) divides (AC) .

The area of (APQ) can be expressed in terms of ratios:

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

if (P) and (Q) are chosen such that (P) and (Q) are proportional along (AB) and (AC) , respectively, and the line (PQ) intersects (BC) at (R) .

Formal Proof via Affine Transformation

Because affine transformations preserve ratios of areas, we can normalize the triangle (ABC) to a convenient coordinate system—for example, position:

- $(A = (0, 0))$,
- $(B = (b, 0))$,
- $(C = (0, c))$.

In this coordinate system:

- (P) lies on (AB) , so $(P = (t b, 0))$, where $(0$
- (Q) lies on (AC) , so $(Q = (0, s c))$, where $(0$

The area of the original triangle:

$$\text{Area}(ABC) = \frac{1}{2} b c.$$

$$\text{Area}(ABC) = \frac{1}{2} b c.$$

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

The area of (APQ) :

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

Sample Problems with Solutions and Explanations

Below are a few representative sample problems designed for 7th class students, illustrating the diversity and depth of olympiad questions.

Problem 1: Number Theory

Question: Find the smallest positive integer that is divisible by 3, 4, and 5, but leaves a remainder of 1 when divided by 6.

Solution Approach:

- Find the LCM of 3, 4, and 5, which is 60.
- The number must be divisible by 60.
- It should leave a remainder of 1 when divided by 6.
- Check multiples of 60: 60, 120, 180, 240...

- $60 \bmod 6 = 0$, so discard.
- $120 \bmod 6 = 0$, discard.
- $180 \bmod 6 = 0$, discard.
- $240 \bmod 6 = 0$, discard.
- Continue to 300: $300 \bmod 6 = 0$, discard.
- The next multiple: 360, 420, 480, ...
- $360 \bmod 6 = 0$, discard.
- $420 \bmod 6 = 0$, discard.
- $480 \bmod 6 = 0$, discard.
- The pattern suggests we need to find a multiple of 60 that leaves remainder 1 when divided by 6.

Alternatively, since the number must be divisible by 60 and leave a remainder 1 when divided by 6, the number can be expressed as:

$$\text{Number} = 60k$$

$$\text{Number} \bmod 6 = (60k) \bmod 6$$

But $60k \bmod 6 = 0$ for any integer k , since 60 is divisible by 6.

Therefore, no such number exists unless the problem is misinterpreted.

Correction: Since $60k$ leaves remainder $0 \bmod 6$, but we want a number divisible by 3, 4, 5, and also with remainder 1 when divided by 6.

Alternative approach:

- Let's find numbers divisible by 3, 4, 5: multiples of 60.
- Now, among these, find the one that leaves a remainder of 1 when divided by 6.

Check $60 + 1 = 61$:

- $61 \bmod 6 = 1$? satisfies the condition.

Now verify if 61 is divisible by 3, 4, or 5:

- $61 \bmod 3 = 1$? no.

- $61 \bmod 4 = 1$? no.
- $61 \bmod 5 = 1$? no.

So, 61 is not divisible by 3, 4, or 5.

Next multiple of 60 plus 1:

- $120 + 1 = 121$:
- $121 \bmod 3 = 1$? no.
- $180 + 1 = 181$:
- $181 \bmod 3 = 1$? no.
- $240 + 1 = 241$:
- $241 \bmod 3 = 1$? no.

Alternatively, since the number must be divisible by 3, 4, and 5, and leave remainder 1 when divided by 6, the key is to find a number n such that:

- $n \equiv 0 \pmod{3}$
- $n \equiv 0 \pmod{4}$
- $n \equiv 0 \pmod{5}$
- $n \equiv 1 \pmod{6}$

Because n is divisible by 3, 4, 5, its LCM is 60, so $n \equiv 0 \pmod{60}$.

Now, check $n \equiv 1 \pmod{6}$:

- For $n \equiv 0 \pmod{60}$, $n \equiv 0 \pmod{6}$, since 60 is divisible by 6.

But $0 \bmod 6 \neq 1$, so no such number exists that is divisible by 3, 4, 5 and leaves a remainder of 1 when divided by 6.

Conclusion: The problem, as constructed, has no solution because the constraints are incompatible.

Educational Note: Such problems teach students to analyze constraints critically, recognize incompatible conditions, and understand the importance of the least common multiple and modular arithmetic.

Problem 2: Geometry

Question: In triangle ABC, the angles at A and B measure 40° and 60° respectively. Find the measure of angle C and construct the triangle.

Solution:

- Sum of angles in triangle ABC = 180° .
- Given angles at A and B: 40° , 60° .
- Therefore, angle C = $180^\circ - (40^\circ + 60^\circ) = 80^\circ$.
- To construct:
- Draw a triangle with angle A = 40° , angle B = 60° .
- Use a protractor to measure these angles at the respective vertices.
- Connect the sides to form triangle ABC with the calculated angles.

Educational Tip: This problem reinforces the basic properties of triangles and the importance of angle sum in geometric constructions.
