Common Questions and Answers from Chapter 15

Below are typical questions from Chapter 15 exercises along with detailed answers, based on the Miller Levine Biology Workbook. These responses are designed to assist students in understanding the material and to serve as a guide for self-study.

Question 1: What is natural selection, and how does it lead to evolution?

Answer:

Natural selection is a process where individuals with certain heritable traits are more likely to survive and reproduce than others due to those traits. Over time, these advantageous traits become more common within the population. This process leads to evolution because it causes changes in the genetic makeup of populations across generations, resulting in adaptations and sometimes the emergence of new species.

Question 2: Describe the role of genetic variation in evolution.

Answer:

Genetic variation refers to differences in DNA sequences among individuals within a population. This variation is crucial because it provides the raw material for evolution. Without variation, natural selection cannot act, as there would be no differences for selection to favor or eliminate. Variations arise from mutations, gene shuffling during sexual reproduction, and gene flow.

Question 3: List and explain the mechanisms that can lead to changes in allele frequencies within a population.

ol>

- **Mutation:** Random changes in DNA that introduce new alleles into a gene pool.
- **Genetic drift:** Random fluctuations in allele frequencies, especially in small populations, due to chance events.
- **Gene flow:** Movement of alleles between populations, which can introduce new genetic material.
- **Natural selection:** Differential survival and reproduction based on traits, leading to increased frequency of advantageous alleles.

Question 4: What evidence supports the theory of evolution?

Answer:

Evidence supporting evolution includes:

- Fossil records: Show gradual changes in species over millions of years.
- Homologous structures: Similar anatomical features in different species suggest common ancestry.
- Molecular biology: Similar DNA and protein sequences among species indicate evolutionary relationships.
- Biogeography: Distribution of species across different regions reflects historical patterns of migration and evolution.
- Vestigial structures: Remnants of features that served a function in ancestors, like human tailbones.

Question 5: Explain how speciation occurs.

Answer:

Speciation is the formation of new and distinct species in the course of evolution. It typically occurs when populations of a species become reproductively isolated due to geographic barriers, behavioral differences, or temporal separation. Over time, genetic differences accumulate, and reproductive barriers develop, preventing interbreeding even if the populations come into contact again.
