- Upon completion, acidify the mixture with dilute HCl to precipitate the corresponding acid (benzoic acid).

- Filter, wash, and dry the product for further analysis.

Reaction Mechanism of Benzonitrile Hydrolysis

Understanding the reaction mechanism provides insight into the chemical transformations during hydrolysis. The process involves nucleophilic attack on the electrophilic carbon of the nitrile group, followed by successive proton transfers and bond cleavages.

Acid-Catalyzed Hydrolysis Mechanism

- The protonation of the nitrile nitrogen increases the electrophilicity of the carbon atom.
- Water acts as a nucleophile, attacking the protonated nitrile carbon to form an imidic acid intermediate.
- Proton transfers facilitate the conversion of the imidic acid to an amide intermediate.
- Further hydrolysis under acidic conditions leads to the formation of a carboxylic acid, with the release of ammonia or an amine derivative.

Base-Catalyzed Hydrolysis Mechanism

- The hydroxide ion attacks the nitrile carbon directly, forming a cyanohydrin-type intermediate.
- Hydrolysis of the intermediate yields the corresponding amide, which is subsequently hydrolyzed further to produce the carboxylate ion.
- Acidification of the reaction mixture then precipitates the free carboxylic acid.

Analytical Techniques and Observations

Thin-Layer Chromatography (TLC)

- Used to monitor the progress of hydrolysis by comparing the R_f values of starting material and products.
- Disappearance of benzonitrile spot indicates reaction completion.

Spectrophotometry

- Measures absorbance related to conjugated systems in the product molecules.
- Provides quantitative data on conversion rates.

Melting Point and Physical Properties

- Characteristic melting points assist in confirming the identity and purity of the products.
- Benzamide and benzoic acid have distinct melting points that serve as identification markers.

Infrared (IR) Spectroscopy

- Benzonitrile exhibits a sharp nitrile stretch around 2220-2260 cm^{-1} .
- Benzamide shows amide carbonyl stretch around 1650 cm^{-1} .
- Benzoic acid displays a broad O-H stretch around 2500-3300 cm^{-1} and a C=O stretch near 1700 cm^{-1} .

Results and Discussion

The hydrolysis of benzonitrile under both acidic and basic conditions successfully converts the nitrile to respective compounds, benzoic acid and benzamide. The reaction conditions, such as temperature, pH, and reaction time, significantly influence the yield and purity of the products.

In acidic hydrolysis, the reaction proceeds smoothly, but care must be taken to prevent over-hydrolysis or side reactions. The formation of benzoic acid is confirmed via melting point analysis, IR spectroscopy, and TLC. Similarly, basic hydrolysis yields benzoic acid after acidification, with TLC confirming the disappearance of starting material.

The reaction mechanism elucidates the nucleophilic attack on the nitrile carbon, facilitated by protonation or hydroxide attack depending on the pH. The intermediate steps align with established organic reaction pathways.

Conclusion

The hydrolysis of benzonitrile exemplifies a crucial transformation in organic chemistry, demonstrating how nitriles can be converted into valuable carboxylic acids or amides under controlled conditions. Both acid- and base-catalyzed hydrolysis pathways are effective, with each offering specific advantages and considerations. The experimental observations, combined with analytical techniques like TLC, IR, and melting point analysis, confirm successful conversion and product purity.

This lab not only reinforces fundamental concepts of nucleophilic addition, hydrolysis mechanisms, and functional group transformations but also emphasizes the importance of reaction conditions in optimizing yields and selectivity. Such knowledge is vital for synthetic organic chemists engaged in

designing pathways for complex molecule synthesis.
